## TODO LIST

---

- change the matrix coefficient indexing to  $a_p^{u_i,p}$  like in [14].
- extend nomenclature
- align equations using the **alignat** environment
- check pressure correction equation on iteration indices (gradients)
- check simple chapter, since the right hand side lacks of deferred corrector and under-relaxed velocities
- mention the boundary conditions for the pressure correction
- extend algorithms to handle passive scalars
- check all headings for correct spelling
- mention that for an unknown velocity field the partial differential equation for the temperature is non-linear as well
- consistent use of either temperature or energy equation
- check the signs in the Boussinesq approximation
- pressure weighted interpolation method for large body forces?
- not only speed but also improvement of robustness
- instationary flows?
- align exponents in the equation for the Newton-Raphson linearization
- use temperature-TO-velocity coupling
- define the term consistent
- add citations to clipper, opencascade and maple, ICEM CFD
- appendix with tables
- errors for velocity all in one single table with multiple rows for each resolution
- column for order of accuracy in tables
- a priori exact solution use this formulation
- Falsche Wahl der problem domain, führt zu global nicht erfüllter kontinuieritätsgleichung. residuum der druckkorrektur entspricht dem massenfluss
- reference Comparison of finite-volume numerical methods with staggered and colocated
- read klajj again and use some of its arguments grids

Figure 6: Fehlerverlauf für ein sukzessiv verfeinertes Gitter

## 8 Comparison of Solver Concepts

### 8.1 Convergence Behaviour on Locally Refined Block Structured Grids with Different Degrees of Coupling

Show how the implicit treatment of block boundaries maintains (high) convergence rates. Plot Residual over number of iterations. Plot Wall time for a single block using SIP, KSP, COUPLED for different grid resolutions.

### 8.2 Parallel Performance

#### 8.2.1 Employed Hardware and Software – The Lichtenberg-High Performance Computer

The Lichtenberg-High Performance Computer, also known as *HHLR* (*Hessischer Hochleistungsrechner*)

- Networking
- Mem Section and processes in between islands (calculating across islands)
- Versioning information (PETSc, INTEL COMPILERS, CLIPPER, MPI IMPLEMENTATION, BLAS/LAPACK)
- Software not designed to perform well on desktop PCs.

#### 8.2.2 Measures of Performance

- Maße definieren
- Nochmal Hager, Wellein studieren
- Guidelines for measuring performance (bias through system processes or user interaction), only measure calculation time do not consider I/O in the beginning and the end
- Cite Schäfer and Peric with their different indicators for parallel efficiency, load balancing and numerical efficiency

#### 8.2.3 Preliminary Upper Bounds on Performance – The STREAM Benchmark

Scientific applications that solve partial differential equations rely on sparse matrix computations, which usually exhibit the sustainable memory bandwidth as bottleneck with respect to the runtime performance of the program [28]. The purpose of this section is to establish a frame in terms of an upper bound on performance in which the efficiency developed solver framework can be evaluated critically. As common measure for the maximum sustainable bandwidth, low-level benchmarks can be used, which focus on evaluating specific properties of the hardware architecture to be used. In this case the STREAM benchmark suite provides apt tests, which are designed to work with data sets that exceed the cache size of the involved processor architecture. This forces the processors to stream the needed data directly from the

memory instead of reusing the data residing in their caches. These types of tests can be used to calculate an upper bound on the memory bandwidth.

In terms of parallel scalability, the STREAM benchmark can also be used as an upper performance bound. According to [4] the parallel performance of memory bandwidth limited codes correlates with the parallel performance of the STREAM benchmark, i.e. a scalable increase in memory bandwidth is necessary for scalable application performance. The intermediate results of the benchmark can then be used to test different configurations that bind hardware resources to the involved processes. Before presenting results the different binding configurations will be explained.

The first configuration sequentially binds the processes to the cores beginning on the first socket. When every core has a bound process the binding algorithm binds the following processes to cores of the second socket. The second configuration binds the processes in a round robin manner regarding the sockets. The this configuration in difference to the second configuration binds one process to three cores. Figure REFERENCE demonstrates the different binding options for two sockets and processors with twelve cores when 8 processes are to be bound to the resources.

**Figure 7:** Block structured grid consisting of two blocks

**Figure 8:** Block structured grid consisting of two blocks

Pinning of processes (picture), preliminary constraints by hardware and operating systems, identification of bottlenecks and explain possible workarounds, history and results of STREAM. Bandwidth as Bottleneck, how to calculate a Speedup estimate based on the measured bandwidth. PETSc Implementation of STREAM

#### 8.2.4 Discussion of Results for Parallel Efficiency

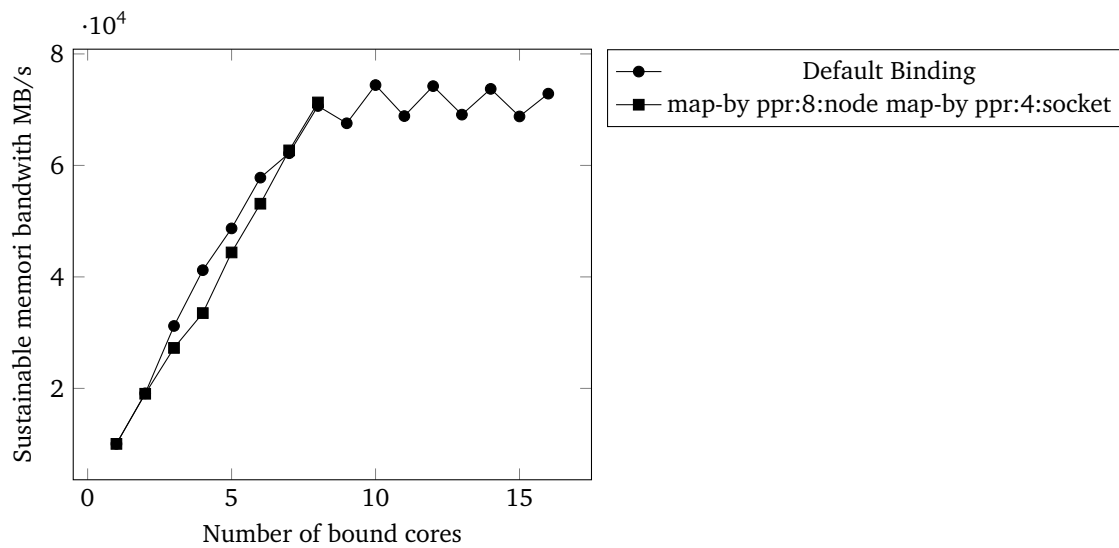

#### 8.2.5 Speedup Measurement for Analytic Test Cases

### 8.3 Test Cases with Varying Degree of Non-Linearity

As Peric says I want to prove that the higher the non-linearity of NS, the better relative convergence rates can be achieved with a coupled solver. Fi

**Figure 9:** Block structured grid consisting of two blocks

**Figure 10:** Sustainable memory bandwidth for the STREAM benchmark (Triad) for different binding options on MPI1

### 8.3.1 Transport of a Passive Scalar – Forced Convection

### 8.3.2 Buoyancy Driven Flow – Natural Convection

### 8.3.3 Flow with Temperature Dependent Density – A Highly Non-Linear Test Case

Maybe I could consider two test cases, one with oscillating density and one with a quadratic polynomial. Interesting would be also to consider the dependence of convergence on another scalar transport equation

## 8.4 Realistic Testing Scenarios – Benchmarking

Also consider simple load balancing by distributing matrix rows equally

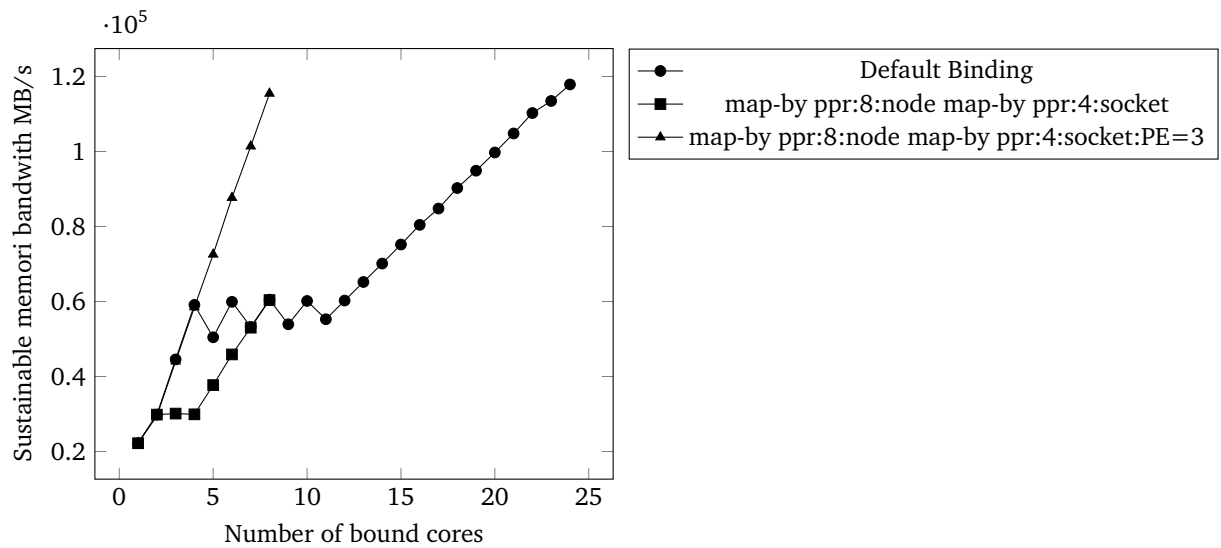

### 8.4.1 Flow Around a Cylinder 3D – Stationary

Describe Testing Setup (Boundary conditions and grid). Present results and compare them with literature.

### 8.4.2 Flow Around a Cylinder 3D – Instationary

- [http://www.featflow.de/en/benchmarks/cfdbenchmarking/flow/dfg\\_flow3d/dfg\\_flow3d\\_configuration.html](http://www.featflow.de/en/benchmarks/cfdbenchmarking/flow/dfg_flow3d/dfg_flow3d_configuration.html)

Describe Testing Setup (Boundary conditions and grid). Present results and compare them with literature.

**Figure 11:** Sustainable memory bandwidth for the STREAM benchmark (Triad) for different binding options on MPI1

#### 8.4.3 Heat-Driven Cavity Flow

- [http://www.featflow.de/en/benchmarks/cfdbenchmarking/mit\\_benchmark.html](http://www.featflow.de/en/benchmarks/cfdbenchmarking/mit_benchmark.html)

Describe Testing Setup (Boundary conditions and grid). Present results and compare them with literature.

#### 8.5 Realistic Testing Scenario – Complex Geometry
